Assignment #1

1. Required Fields

The name should be rejected when it is empty because the registration needs to know who is submitting the form. The terms of agreement should also be rejected when it is unchecked because the student must acknowledge and accept the conditions before registering. The validation rule for the name is that the field cannot be blank, while the rule for the agreement is that the checkbox must be selected. A useful message for the name is "Please enter your full name.", while the message for the agreement can be "Please check the box to accept the terms for continuing."

2. Password Confirmation

The repeated password needs its own check because the first password may follow all the security requirements but the student could accidentally type something different the second time. The two passwords should be exactly the same, following the capital letters, numbers, and symbols. "Batumbading@2026" is an example password that meets the requirements, while "Batumbaka1u7" fails because it doesn't contain one of the required symbols. Overall, every character is important in creating a password, wherein without a 'Confirm Password' a user typo during creation of password, would potentially lock them out of their own account on their next login.

3. Purpose of Regular Expressions

A regular expression is like a security guard checking tickets at an entrance, it looks for the expected details and format before allowing something to pass. For example a date field can require a format such as month, day, and year in a specific order, while StudentID field can require a particular number of letters and digits. It checks whether the information follows the expected pattern, but it does not necessarily prove that the information is genuine or belongs to the person entering it.

4. Philippine Mobile Number Formats

09171274567 is accepted because it begins with 09 and has exactly 9 more digits. While +639171274567 is also accepted because the prefix +63 is the international country calling code assigned to the Philippines and is followed by 9 digits. 0917-127-4567 is rejected because it contains hyphens, and probably the developer didn't put a code for input sanitization that automatically removes hyphens, brackets, empty spaces, while 0917127456 is rejected because it does not have enough digits. Even if a number has the correct format, this does not confirm that the number is currently active or that it belongs to the student because format checking only examines how the number is written.

5. Accessibility and Security

Descriptive error messages are useful because they tell users what ~~what~~ went wrong and how they can fix it instead of depending only on a red border because users who cannot see color (colorblind), including many screen reader users may not know that a field has a problem or how to fix it. For example, saying "Enter a valid mobile number with 11 digits" give much clearer guidance than simply changing the border color. The HTML attribute 'aria-describedby' can connect a form field with text that describes its error or instructions. The server must still validate the information because browser/client validation can be bypassed, so relying only on checks performed on the user's device would not be secure.
